Abstract

We previously reported the activation profiles of the human kallikrein-related peptidases (KLKs) as determined from a KLK pro-peptide fusion-protein system. That report described the activity profiles of 12 of the 15 mature KLKs versus the 15 different pro-KLK sequences. The missing profiles in the prior report, involving KLK9, 10, and 15, are now described. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis, mass spectrometry, and N-terminal sequence analyses show that KLK9 and 10 exhibit low hydrolytic activities towards all of the 15 pro-KLK sequences, while KLK15 exhibits significant activity towards both Arg- and Lys-containing KLK pro-sequences. The ability of KLK15 to activate pro-KLK8, 12, and 14 is confirmed using recombinant pro-KLK proteins, and shown to be significant for activation of pro-KLK8 and 14, but not 12. These additional data for KLK9, 10, and 15 now permit a completed KLK activome profile, using a KLK pro-peptide fusion-protein system, to be described. The results suggest that KLK15, once activated, can potentially feed back into additional pro-KLK activation pathways. Conversely, KLK9 and 10, once activated, are unlikely to participate in further pro-KLK activation pathways, although similar to KLK1 they may activate other bioactive peptides.

Keywords: activation cascade; activome; kallikrein; kallikrein-related peptidases (KLKs); protease.
files of 12 of the 15 mature KLKs versus the 15 different pro-KLK sequences; the missing profiles in the prior report, involving KLK9, 10, and 15, are now presented. These additional data for KLK9, 10, and 15 permit a completed KLK activome profile, characterized using a KLK pro-peptide fusion-protein system, to be described.

Under the conditions evaluated (100:1 molar ratio pro-KLK fusion protein:mature KLK, pH 6.0 or 7.4, and for either 1 or 24 h incubations at 37°C) KLK9 and KLK10 exhibited minimal specificity towards hydrolysis of the 15 pro-KLK fusion proteins; however, KLK15 exhibited the ability to hydrolyze several pro-KLK sequences (Figure 1). A summary of the hydrolysis densitometry data for KLK9, 10, and 15 hydrolyses of the 15 different pro-KLK fusion proteins is given in Table 1 and a complete listing of hydrolysis, mass spectrometry, and N-terminal sequencing data are provided as supplementary data.

The hydrolysis results for pro-KLK fusion proteins indicate that after 24 h incubation at pH 7.4 with KLK15, greater than 50% hydrolysis was achieved against pro-KLK1-3, 7–9, 11, and 14–15; a significant sub-set of the pro-KLKs. No hydrolysis was observed for pro-KLK4 and 6 fusion proteins, and hydrolysis of pro-KLK12 resulted in only 12% hydrolysis under these conditions (Table 1). Based upon an available set of expressed and purified recombinant pro-KLK proteins, the ability of KLK15 to activate pro-KLK8, pro-KLK12, and pro-KLK14 was evaluated; the ability of KLK10 to activate pro-KLK14 was also evaluated. A summary of these activation assays is shown in Figure 2. The results confirm that KLK15 is capable of activating pro-KLK8, pro-KLK12, and pro-KLK14, and with a relative ranking of activation efficiency being pro-KLK14 > pro-KLK8 > pro-KLK12. Weak activation of pro-KLK12 by KLK15 was predicted from hydrolysis of the pro-KLK fusion protein data, and with the actual pro-KLK12 protein evidence of activation by KLK15 required extended (24 h) incubation (Figure 2). Although the pro-KLK8 fusion protein was hydrolyzed by KLK15 with greater apparent efficiency than the pro-KLK14 fusion protein, this activity is reversed in the hydrolysis of the actual pro-KLK proteins (Figure 2). This result suggests the potential for an exosite interaction between KLK15 and pro-KLK14 that is not present in the pro-KLK fusion protein. The results also indicate that KLK10 exhibits minimally detectable hydrolytic activity versus pro-KLK14.

Combining the results presented here with data from our prior study allows a completed ‘activome’ description of relative hydrolysis rates for the KLK family (Figure 3). This now completed view groups KLK9 and KLK10 with KLK1, in that these KLKs once activated, appear unlikely to feed back into any further KLK activation cascade. As with KLK1, which hydrolyzes the bioactive kinins, KLK9 and 10 may recognize separate bioactive peptide substrates distinct from any pro-KLK family member. In this regard, KLK9 contains an atypical Gly residue at position 189 (Yousef and Diamandis, 2000), located in the base of the substrate S1 pocket. This residue is characteristically Asp in proteases with trypsin-like specificity, including most of the KLKs, and provides an electrostatic selectivity for the basic residues Arg or Lys in the substrate P1 position (present in the majority of KLK pro-sequences). Thus, Gly189 is likely responsible for the inability of KLK9 to hydrolyze the pro-KLK proteins; the specificity of KLK9 remains undetermined, but does not include the KLK pro-sequences.

KLK10 is unique among the KLK family in that it contains a Ser residue at position 193, which is present as a characteristically conserved Gly residue in serine proteases (Liu et al., 1996). The main chain amide of Gly193 participates in stabilization of the oxyanion intermediate.

**Table 1** Percent hydrolysis of pro-KLK(1–15) fusion proteins for 100:1 molar ratio incubation with mature KLK9, 10, and 15 at pH 6.0/7.4 for 1 h and 24 h at 37°C.

Mature KLK10 and KLK15 proteins were expressed from an Escherichia coli host, refolded and purified as previously described (Debela et al., 2006). Mature KLK9 was expressed as recombinant protein from HEK293 human embryonic kidney epithelial cells as the expression host, as previously described for pro-KLK6 (Yoon et al., 2008). The pro-KLK9 was activated to mature KLK9 by incubation with enterokinase, as previously described for activation of pro-KLK6 (Blaber et al., 2007). Assay conditions utilized 40 mM of pro-KLK fusion proteins as previously described (Yoon et al., 2007).
in the hydrolytic reaction of peptide substrates. Schmidt and coworkers studied the catalytic effects of a Glu mutation at position 193 in coagulation factor XI, identified from a genetically inherited deficiency in factor XI activity (Schmidt et al., 2004). Their results showed that substitution of Gly193 by Glu reduced $k_{cat}$ by several orders of magnitude, and likely distorted the critical stereochemistry of the oxyanion binding pocket. Ser193 in KLK10 may similarly distort the oxyanion binding pocket, resulting in significant reduction in overall catalytic activity. Thus, KLK10 may therefore be an essentially inactive protease, or may have an as-yet unidentified substrate.

KLK15 is unique among the KLKs in having a Glu residue at position 189 in the base of the substrate S1 pocket (Yousef et al., 2001). Evnin and coworkers have reported that Arg/Lys selectivity in trypsin can be shifted 35-fold in favor of Lys by an Asp→Glu mutation at position 189 (Evnin et al., 1990). KLK15 exhibits the highest efficiency of hydrolysis against its own pro-peptide sequence (and is therefore predicted to be subject to autocatalytic activation), followed by KLK8 and KLK7 (Table 1). These KLK pro-peptides all contain a Lys in the P1 position, and the results indicate that the Glu at position 189 influences the Arg/Lys preference in favor of recognition of Lys, as predicted by the results of Evnin and coworkers (although KLK15 retains the capability of activating Arg-containing pro-KLK sequences). Thus, KLK15 is hypothesized to participate in activation cascades involving other members of the KLK family, particularly those with Lys-containing pro-peptides, with the notable exception of pro-KLK6, and weak activation potential against pro-KLK12. The ‘P’ and ‘P-prime’ residue positions of the pro-KLKs play a key role in their recognition and hydrolysis and are uniquely different. In this regard, pro-KLK6 is distinct in containing a His residue in the P3 position; similarly, pro-KLK12 contains a unique sequence in the P4-P2 positions. The stereochemical complementarities of these positions in the
corresponding KLK15 ‘S’ and ‘S-prime’ sites appear energetically unfavorable for recognition and hydrolysis. KLK15 is robustly expressed in the thyroid, but is also detectable in the prostate, salivary glands, adrenal glands, colon, testis, and kidney (Yousef et al., 2001). Other members of the KLK family expressed in thyroid include KLK2–5, 7, 11–14 (Yousef and Diamandis, 2001); of these, pro-KLK7 and pro-KLK12–15 contain a Lys at the activation P1 position, and (with the exception of KLK12) are hydrolyzed most efficiently by KLK15 (Table 1). The presence of KLK4, 5, and 12 in thyroid provide pathways to activate pro-KLK15 (in addition to the auto-lytic activation potential of KLK15). Thus, activating cascades involving these members of the KLK family appears likely in thyroid, as well as other tissues, including prostate.
